Correlation

Jonathan A. Pedroza, PhD

Modeling Relationships

$$outcome_i = (model) + error_i \\$$

$$outcome_i = (b_1 X_i) + error_i$$

if we work with standardized scores (what are those called?) then the equation changes because the predictor and outcome have a mean of 0

Modeling Relationships

we would lose the intercept so what is left over is the following equation

$$z(outcome)_i = b_1 z(X_i) + error_i$$

 \blacktriangleright wit this equation the outcome can be presented as a standardized score predicted by a standardized variable multiplied by b_1

Modeling Relationships

- when using standardized scores, the value becomes a pearson product-moment correlation coefficient
 - pearson product-moment correlation coefficient = correlation coefficient
 - ightharpoonup denoted with a r
 - \triangleright which means the correlation coefficient or r is standardized

Covariance

- simply put, covariance is an un-standardized correlation
- to understand covariance, we must look at variance

$$S^2 = \frac{\sum_{i=1}^n (X_i - X)^2}{N-1} = \frac{\sum_{i=1}^n (X_i - X)(X_i - X)}{N-1}$$

- covariance is the examination of the relationship between two variables
 - ▶ if one variable deviates from its mean, the other variable should either deviate from its mean in the same direction or in the opposite direction

Covariance

- for variance, we _____ our deviations
 - for covariance, we multiply the deviation of one variable by the deviation for the second variable
 - positive values indicate a relationship in the same direction
 - negative values indicate a relationship where the deviations are in opposite directions
- multiplying deviations of one variable by the deviations of a second variable provides cross-product deviations
- $lackbox{ we then get the average by dividing by the degrees of freedom <math>(N-1)$

$$covariance(x,y) = \frac{\sum_{i=1}^{n}(x_i - \overline{x})(y_i - \overline{y})}{N-1}$$

[1] -10.6

$$covariance(x,y) = \frac{-10.6}{4}$$

-10.6/4

[1] -2.65

$$covariance(x,y) = -2.65$$

- since this is a negative covariance, which of the following would be true
 - both variables deviated from the mean in the same direction
 - one variable deviated away from the mean (increased) while one variable deviated from the mean in the opposite direction (decreased)

- **standardization** is the process of converting the covariance into standardized units
 - the unit of measurement we are looking for are standard deviation units
 - > standard deviation is the average deviation from the mean
- to standardize our covariance, we would divide by the standard deviation
 - we have 2 standard deviations though
 - just like with our deviations, we are going to multiply our standard deviations

- so our covariance value is divided by the product of our multiplied standard deviations
 - this is known as a correlation coefficient

$$r = \frac{cov_{xy}}{S_xS_y} = \frac{\Sigma(x_i - \overline{x})(y_i - \overline{y})}{(N-1)S_xS_y}$$

this correlation coefficient is the Pearson product-moment correlation coefficient or simply Pearson's correlation coefficient or r

- ▶ by standardizing our covariance, we now can only have values that go from -1 to 1
 - these are seen by the strength of the relationship
 - r = 0 ->no correlation
 - ightharpoonup r = .1 is a small/weak correlation/effect size
 - ightharpoonup r = .3 is a moderate/medium correlation/effect size
 - ightharpoonup r = .5 is a large correlation/effect size

- JP: while these values can go from -1 to 1, negative and positive values don't matter in regard to strength
 - ightharpoonup r = -.8 is a larger correlation than r = .6
 - the larger number will always be the larger correlation
 - negative values only indicate direction
 - ightharpoonup r = -.8 is a large negative/inverse correlation
- when we examine a correlation between two variables, we are using a **bivariate correlation**

Significance of Correlation Coefficient

- lacktriangle the issue with the sampling distribution for Pearson's r is that the sampling distribution is not normal
 - to fix this, we can adjust the sampling distribution to be normal by using z-scores

$$z_r = \frac{1}{2}log_e(\frac{1+r}{1-r})$$

 \blacktriangleright the z_r also has a standard error by calculating the following equation

$$SE_{z_r} = \frac{1}{\sqrt{N-3}}$$

Significance of Correlation Coefficient

- lacktriangle transform your adjusted r value into a z-score
 - our hypotheses for a correlation is that the correlation will be different from zero
 - as with other tests, rather than subtract zero, we can just have the value divided by the standard error to get a z-score

$$z = \frac{z_r}{SEz_r}$$

 \blacktriangleright we could also use a t-test with a correction in the degrees of freedom (N-2

$$t_r = \frac{r\sqrt{N-2}}{\sqrt{1-r^2}}$$

Some Notes About Correlation Coefficients

- remember that our correlation coefficients do not indicate causality
 - unless the design of your study would indicate a cause -> effect relationship (e.g., experiments), then you can only state that there is a relationship present
 - or state there is evidence of a significant relationship
- this can be due to several reasons
 - directionality of your variables
 - your IV could be your DV and vice versa
 - Ex: depression -> obesity | obesity -> depression
 - is there a third variable or **tertium quid** which could be influencing the relationship between your two variables

Confidence Intervals for r

 \blacktriangleright we can calculate confidence intervals using those z_r values and the corresponding standard errors

$$lower\;CI=\overline{X}-(1.96*SE)$$

$$upper\ CI = \overline{X} + (1.96*SE)$$

becomes

$$lower \; CI = z_r - (1.96*SE_{z_r})$$

$$upper\ CI = z_r + (1.96*SE_{z_r})$$

Confidence Intervals for r

we can then convert these back to correlation coefficients by using the following formula

$$r = \frac{\epsilon^{2z_r} - 1}{\epsilon^{2z_r} + 1}$$

- SPSS does not compute your standard confidence intervals for you
 - to get around this AGAIN we will be using bootstrapped confidence intervals

Bivariate Correlation

- let's talk about some sources of bias
- when fitting a linear model, we want a linear relationship between our variables so we need
 - ▶ an outcome that is numeric/continuous/ratio/interval
 - and a predictor that is also numeric/continuous/ratio/interval
- we'll also look for outliers
 - there are additional correlational tests that can rank the data to deal with outliers
 - JP: I don't think outliers will affect our data anyway
- we'll also look at out P-P and Q-Q plots to make sure the data looks normal

Pearson's Correlation Coefficient Using SPSS Statistics

- we will cover SPSS stuff during the activity section
 - if you square your correlation coefficient you get your coefficient of determination
 - which is the amount of variability in one variable that is shared by the other variable
 - $ightharpoonup R^2$

Spearman's Correlation Coefficient

- **Spearman's correlation coefficient**, denoted as r_s , is a non-parametric statistic that can be useful for minimizing effects of extreme scores (outliers) or violations of assumptions
- rquires only ordinal data for both variables
 - lacksquare pronounced as rho or ho
- it works by ranking the data of your variables and then applies the Pearson's correlation coefficient equation to those ranks
- we will look at Spearman's correlation coefficient when conducting correlations in SPSS

Kendall's tau τ (non-parametric)

- non-parametric test that should be used for small datasetswith large number of "tied" ranks
- seen as a better alternative to Spearman's correlation as an estimate of the correlation in the population

Biserial & Point-Biserial Correlations

- Biserial and point-biserial correlation coefficients are similar in that they are correlations where one variable is dichotomous (2 categories)
 - the difference is that dichotomous variable is either discrete or continuous
- ▶ a point-biserial correlation coefficient is used when one variable is a discrete dichotomous variable (sex)
- ▶ biserial correlation coefficient is used when one variable is a continuous dichotomous variable (passing an exam = 1, failing an exam = 0)
 - a variable on a continuum would fall under a biserial correlation coefficient

$$point - biserial = r_{nb}$$

$$biserial = r_b$$
